This problem deals with angular measurements. Using the small angle approximation calculate the distance of a ruler when it subtends 1 degree = .017 radians. Just use the formula below to get your answer for the distance. Don't forget the units on your answer. .017 = 1 foot / L. 4. Our calculated L = Now go out into the hall outside the lab.

In this lab, you will use Earth's diameter in kilometers and a technique called parallax to measure distances to two solar-system objects: an asteroid and the planet Venus. You will then use your measurement of the distance to Venus to determine how many kilometers are in one astronomical unit (AU). One AU is the average distance between

Parallax Measurements and Determining Distances. Students explore the trigonometric parallax technique for determining distances to objects, constructing a simple parallax measurement tool and comparing direct and parallax-derived measurements for distances out to fifty feet. We then apply the basic technique to nearby stars in the Milky Way galaxy, and connect the results to the fundamental distance scale for the universe.

PARALLAX MEASUREMENT. Fig. 1 shows an overhead view of the geometry of a parallax measurement. Such a measurement requires observations from two different places separated by a known distance. This distance, the baseline, is represented by the symbol b . Parallax can be used to measure the distance to nearby stars since they can be measured against background stars, which do not appear to move as far, or in fact at all, due to parallax since they are so far away.
