Inhibin, activin, and follistatin were originally discovered as hormonal fac tors a decade ago. Subsequent studies revealed that they are widely distrib uted anatomically and have multiple biological functions in a wide range of cells and tissues.

Inhibin A, activin A and follistatin in maternal serum. Maternal serum levels of inhibin A were significantly lower (P<0.01) in miscarriage patients compared to the controls. Serum activin A levels tended to be low in the miscarriage patients compared to the controls. However, the difference did not reach statistical significance (P=0.08).

Activin, inhibin, and follistatin proteins were originally reported to be produced in the gonads and believed to influence pituitary gonadotropin synthesis and secretion, especially FSH, but not LH . In this study, we used two hypothalamic cell models, mHypoA-55 and mHypoA-50 Kiss-1-expressing cells. mHypoA-55 cells have characteristics of KNDy neurons in the ARC region of the hypothalamus, and the Kiss-1 gene in these cells was repressed by E2 under certain conditions.

Expression of inhibin, activin or follistatin mRNAs in multiple organs in humans. of FSH/LH stimulators gonadotrophin-releasing hormone (GnRH) and activin and inhibitors (inhibin and follistatin). , when it was established that inhibin and activin share a sequence homology with transforming growth factor-(3 (TGF-(3), roles as growth factors were suggested (Vale et al., 1988).

Recent studies have indicated that inhibins, activins, and follistatin act in concert with gonadotropin-releasing hormone (GnRH) and gonadal steroids to regulate the production and secretion of the pituitary gonadotropins, luteinizing hormone (LH) and follicle-stimulating hormone (FSH). Inhibins, activins, and follistatin were initially identified in gonadal tissues and shown to regulate FSH secretion by endocrine feedback on the anterior pituitary gland.

The changing pattern of granulosa cell expression of inhibin/activin subunits and follistatin during follicle development and their differential regulation by extrinsic and intraovarian factors supports evidence from functional studies, mostly in vitro, that these proteins have important roles in folliculogenesis, oocyte maturation and corpus luteum function.

It has also emerged that (i) inhibins and activins are members of the diverse but structurally related transforming growth factor beta (TGF beta) peptide family; (ii) follistatin, although structurally unrelated to the TGF beta family, modulates activin bioactivity by acting as a specific high-affinity binding protein; (iii) inhibins, activins, and follistatin function as intragonadal autocrine/paracrine regulators of follicle cell differentiation and steroidogenesis; (iv) inhibins, activins

Activin and inhibin are two closely related protein complexes that have almost directly opposite biological effects. Identified in 1986, activin enhances FSH biosynthesis and secretion, and participates in the regulation of the menstrual cycle. Many other functions have been found to be exerted by activin, including roles in cell proliferation, differentiation, apoptosis, metabolism, homeostasis, immune response, wound repair, and endocrine function. Conversely, inhibin downregulates FSH synthes

Abstract. The family of inhibin-related proteins has been investigated extensively in the last decade. It is composed of three members: inhibin, activin and follistatin. Inhibin and activin are chemically related, while follistatin acts as an activin-binding protein. Initially identified as regulators of pituitary follicle stimulating hormone (FSH) secretion, inhibin, activin and follistatin have more recently been characterized as growth factors, embryo modulators and immune factors.

Follistatin is an autocrine glycoprotein that is expressed in nearly all tissues of higher animals. Its primary function is the binding and bioneutralization of members of the TGF-β superfamily, with a particular focus on activin, a paracrine hormone. An earlier name for the same protein was FSH-suppressing protein (FSP).

The synthesis of inhibin α and βC subunits within cells producing either activin βA or βB subunits leads to inhibitory dimer formation and decreases production of signaling-active activin. Potent and abundant extracellular, soluble regulators also include follistatin and follistatin-like3 (also termed FSTL3 and follistatin-related protein).

The autocrine/paracrine function of the activin-binding proteins, follistatins, constitutes an important local mechanism to modulate activin bioactivity while the restricted actions of gonadal inhibins to betaglycan-expressing gonadotropes provides a secondary mode of regulation of cell-specific actions of activins.
