A particle accelerator is a machine that uses electromagnetic fields to propel charged particles to very high speeds and energies, and to contain them in well-defined beams. Large accelerators are used for basic research in particle physics. The largest accelerator currently operating is the Large Hadron Collider near Geneva, Switzerland, operated by the CERN. It is a collider accelerator, which can accelerate two beams of protons to an energy of 6.5 TeV and cause them to collide head-on, creati

Particle accelerator - Wikipedia

Particle accelerators are essential tools of discovery for particle and nuclear physics and for sciences that use x-rays and neutrons, a type of neutral subatomic particle. Particle physics, also called high-energy physics, asks basic questions about the universe. With particle accelerators as their primary scientific tools, particle physicists have achieved a profound understanding of the fundamental particles and physical laws that govern matter, energy, space and time.

Unlike traditional accelerators, which employ only one particle beam, wakefield accelerators use two beams. Like a speedboat rushing over a lake, each drive bunch – the first beam -- leaves behind an electromagnetic wake, which creates an electric gradient that is then used to accelerate the main beam. Although the construction of a large-scale particle accelerator based on wakefield acceleration is still at least several years off, the technology promises to dramatically reduce the size ...
