Background and aims: The biological characterization of childhood acute myeloid leukemia (c-AML) is an important outcome predictor. In Brazil, very little is known about the frequency of AML subgroups, although c-AML accounts for about 18% of leukemias. We carried out this study to investigate the contribution of type I and II gene mutations in the probability of overall survival (pOS) of c-AML in Brazil.

Acute myeloid leukemia (AML) is a genetically heterogeneous disease with accumulation of acquired genetic alterations in hematopoietic progenitor cells that disturb normal mechanisms of cell growth, proliferation and differentiation. 1 Clonal chromosome alterations are detected in approximately 55% of adults with AML, and presenting cytogenetic alterations have long been recognized as the strongest prognostic factor for response to therapy and survival.

Acute myeloid leukemia (AML) is a clinically heterogeneous disease, yet it is one of the most molecularly well-characterized cancers. Risk stratification of patients currently involves determination of the presence of cytogenetic abnormalities in combination with molecular genetic testing in a few genes.

Philadelphia chromosome-positive (Ph+) acute myeloid leukemia (AML) is a controversial diagnosis, as others propose that it represents chronic myelogenous leukemia in blast phase (CML-BP). Conversely, ABL1 mutations occur in 25% of imatinib-naïve patients with CML-BP but are not described in patients with AML.
