A Guide For Ultrasonic Testing

Ultrasonic nondestructive testing (NDT) is a method used to characterize the internal volumes of materials. It works by propagating high-frequency sound waves well above the range of human hearing throughout the material. It can be used to detect flaws and discontinuities in metals, composites, and other materials.

Ultrasonic Testing Overview | Zetec

Ultrasonic Testing (UT) uses high frequency sound energy to conduct examinations and make measurements.

Ultrasonic inspection can be used for flaw detection/evaluation, dimensional measurements, material characterization, and more. To illustrate the general inspection principle, a typical pulse/echo inspection configuration as illustrated below will be used.

Introduction to Ultrasonic Testing

Introduction Ultrasonic sensors work by transmitting a pulse of sound, much like sonar detectors, outside the range of human hearing. This pulse travels away from the range finder in a conical shape at the speed of sound (340 m/s). The sound reflects off an object and back to the range finder.

By using a high-frequency sound wave to discover and map anomalies, ultrasonic testing (UT) shows the minutest damage on and below the surface. Technicians can get a full 3D picture of an anchor bolt, detecting where damage has occurred with precision. The benefit of ultrasonic testing for anchor bolts is that there is no one set solution. There's only the right combination of tools for your specific needs.

Ultrasonic testing (UT) is being used to detect leaking BWR and PWR fuel rods. The testing method makes use of differences in scattering by water and gas of ultrasonic (pressure) waves as they are reflected between the inner and outer surfaces of fuel cladding. The UT process makes use of two probes, which move laterally across a FA.

Ultrasonic Testing - an overview | ScienceDirect Topics

Ultrasonic probes used for weld examination have frequencies generally between 2MHz and 5MHz, the lower frequency probes being used for the examination of coarse grained material or on rough surfaces, the higher frequency probes for the detection of fine defects such as cracks or lack of fusion.

The area effective for the ultrasonic test is called the "sound beam" which is characteristic for the applied probe and material in which sound waves propagate. A sound beam can be roughly divided into a convergent (focusing) area, the near-field, and a divergent (sp reading) part, the far field, Fig. 3.

Nondestructive Material Testing with Ultrasonics

Ultrasonic testing is completely nondestructive. The test piece does not

have to be cut, sectioned, or exposed to damaging chemicals. Access to only one side is required, unlike measurement with mechanical thickness tools like

calipers and micrometers. There are no potential health hazards associated with ultrasonic testing, unlike radiography.
