We review some of the fundamental concepts which have been introduced into the field of amorphous semiconductors by Professor Sir Nevill Mott. These include the $8-N$ rule, variable range hopping, the Austin-Mott conductivity, the mobility edge, and the minimum metallic conductivity. We demonstrate that there are still severe problems, although there is no real

alternative to Mott's concepts.

Our understanding of amorphous semiconductors has been greatly clarified by recent theoretical and experimental work. It is now evident that the electrical properties of these materials are generally controlled by intrinsic defects which are either thermodynamically required or induced via strains during the deposition process.

A semiconductor material has an electrical conductivity value falling between that of a conductor, such as metallic copper, and an insulator, such as glass. Its resistivity falls as its temperature rises; metals are the opposite. Its conducting properties may be altered in useful ways by introducing impurities into the crystal structure. When two differently-doped regions exist in the same crystal, a semiconductor junction is created. The behavior of charge carriers, which include electrons, ion
