However, the transistor's small signal output resistance, r_o , is not typically high enough for a reasonable transconductance amplifier (ideally infinite). Nor is the output load, R_L , low enough for a decent voltage amplifier (ideally zero). Another major drawback is the amplifier's limited high-frequency response due in part to the built ...

Where $A_{V,mid}$ is called the midrange gain and represents the maximum gain of the amplifier in its frequency working range, for example 20 Hz - 20 kHz for an audio amplifier. Therefore, when $A_{V,mid} = A_V$, the normalized gain (written indifferently A_V) is $A_V(\text{dB}) = 0$. This sets a 0 dB reference when the gain is maximum.

The number of output transistor an amp uses can dictate how well it moves the speaker. For example, when you compare an amp with 4 output transistors (2 for positive waveform and 2 for negative waveform) with an amplifier that has 12 output transistors, the transistors on the 12 amp will work 1/3 as hard for the amp to push the same amount of ...
