Description. CHAPTER 13 MOLECULAR SPECTROSCOPY Our most detailed knowledge of atomic and molecular structure has been obtained from spectroscopy—study of the emission, absorption and scattering of electromagnetic radiation accompanying transitions among

atomic or molecular energy levels. Whereas atomic spectra involve only electronic transitions, the spectroscopy of molecules is more intricate because vibrational and rotational degrees of freedom come into play as well.

Nuclear magnetic resonance (NMR) spectroscopy in a clinical setting is the study of the specific resonance frequencies absorbed by a sample or tissue. These frequencies are related to the specific molecules present and can therefore be used to assess the disease state of a tissue.

Raman spectroscopy has become a routine technique in gemmological laboratories since the late 1990s. It is mostly used for identification of inclusions and this is of interest in determining the geographical origin of a gem by means of specific inclusions or mineral associations.
