Ebola And Marburg Viruses Molecular

This book focuses on current research into both Ebola and Marburg viruses. Emphasis is placed on the genomics of the viruses, their molecular properties and their taxonomy. Further chapters consider how the viruses evolve and replicate and there are discussions on the spread of these viruses and their pathogenicity. This book presents a comprehensive review of the current research on these highly virulent viruses.

Ebola and Marburg viruses: molecular and cellular biology.

Molecular evolutionary analyses for Ebola and Marburg viruses were conducted with the aim of elucidating evolutionary features of these viruses. In particular, the rate of nonsynonymous substitutions for the glycoprotein gene of Ebola virus was estimated to be, on the average, 3.6×10^{-5} per site per year. Marburg virus was also suggested to be evolving at a similar rate.

Filoviruses like Ebola and Marburg are important human pathogens, and they have fascinating filamentous virion structures that are organized by the VP40 protein. The manuscript by Briggs and colleagues now describes the molecular architecture of VP40 in Ebola and Marburg filovirus-like particles and in fixed Marburg virus particles.

Infection with Marburg and Ebola viruses cause haemorrhagic fevers that are characterized by organ malfunction, bleeding complications, and high mortality. The viruses are members of the family Filoviridae, a group of membrane-enveloped filamentous RNA viruses. Five distinct species of the genus Ebolavirus have been reported; the genus Marburgvirus contains only one species.

Unlike the case with Marburg virus isolates, the GP genes of all known EBO viruses have an unusual organization in that the GP is encoded in 2 frames (0 and -1 frames), which become linked

(expressed) by transcriptional editing in ~25% of the transcripts. As a result of this organization, a smaller, nonstructural, secreted, soluble GP (SGP) is expressed as the predominant gene product and ...

Detection and Molecular Characterization of Ebola Viruses ...

Abstract. Filoviruses, represented by the genera Ebolavirus and Marburgvirus, cause a lethal hemorrhagic fever in humans and in nonhuman primates. Although filovirus can replicate in various tissues or cell types in these animals, the molecular mechanisms of its broad tropism remain poorly understood. Here we show the involvement of members of the Tyro3 receptor tyrosine kinase family-Axl, Dtk, and Mer in cell entry of filoviruses.

Tyro3 family-mediated cell entry of Ebola and Marburg viruses

The Ebola and Marburg filoviruses are among the most pathogenic viruses in the world. They are responsible for outbreaks of hemorrhagic fevers in human and nonhuman primates, as well as other vertebrates, causing many deaths (Feldmann et al., 2003, Leroy and Gonzalez, 2012). Some parts of Africa are particularly affected by outbreaks.

Abstract: Ebola and Marburg viruses, family Filoviridae, are among the best known examples of emerging and re-emerging pathogens. Although

outbreaks have been sporadic and geographically restricted to areas of Central Africa, the hemorrhagic fevers caused by these viruses are remarkably severe and are associated with high case fatality rates often exceeding 80 percent.

Ebola is a member of the negative-stranded RNA virus family Filoviridae. These filoviruses (Ebola, Marburg and

Reston) are very similar in morphology, density and sodium dodecyl sulfate - polyacrylamide gel electrophoresis (SDS-PAGE) profile (Klenk, 1994). The particles are pleomorphic, meaning they can exist in many shapes.
