Regression models are useful for making predictions for new observations not include in the originaldataset. If the model is good, the predictions should be close to the true value of the response variable for this observation, however it may not be exact, i.e. $\hat{y}$ might be different than y .

The aim of linear regression is to model a continuous variable Y as a mathematical function of one or more X variable (s), so that we can use this regression model to predict the Y when only the X is known. This mathematical equation can be generalized as follows: $Y = \beta_1 + \beta_2 X + \epsilon$ where, β_1 is the intercept and β_2 is the slope.

Linear regression. In statistics, linear regression is a linear approach to modelling the relationship between a scalar response (or dependent variable) and one or more explanatory variables (or independent variables). The case of one explanatory variable is called simple linear regression. For more than one

explanatory variable, the process is called multiple linear regression.
