In physics, a partition function describes the statistical properties of a system in thermodynamic equilibrium. Partition functions are functions of the thermodynamic state variables, such as the temperature and volume. Most of the aggregate thermodynamic variables of the system, such as the total energy, free energy, entropy, and pressure, can be expressed in terms of the partition function or its derivatives. The partition function is dimensionless, it is a pure number. Each partition function

In mathematics, a graph partition is the reduction of a graph to a smaller graph by partitioning its set of nodes into mutually exclusive groups. Edges of the original graph that cross between the groups will produce edges in the partitioned graph. If the number of resulting edges is small compared to the original graph, then the partitioned graph may be better suited for analysis and problem-solving than the original. Finding a partition that simplifies graph analysis is a hard problem, but one

Normal factor graphs For a normal realization of a partition function, a natural graphical model is a normal factor graph (NFG), in which vertices are associated with factors, ordinary edges (i.e., hyperedges of degree 2) are associated with internal variables, "half-edges" (i.e., hyperedges of degree 1) are associated with external variables, and a variable edge or half-edge is incident on a factor vertex if the variable is involved in that factor.

Partition functions are a class of polynomials with combinatorial coefficients that count weighted combinatorial structures. Originally introduced in statistical physics, they have more recently found widespread application in combinatorics, theoretical computer science, statistics and machine learning, and have become a vibrant research area in their own right.

The partition function of the Q-state Potts model [217] on, e.g., the square lattice, with a second order critical point for Q ∈ [0, 4], has a Fortuin-Kasteleyn (FK) representation at the CP [218]: Z Potts = ∑ u (C) Q 1 2 N P, where the configurations u(C) are those of unions of FK clusters on the square lattice, with a total number N P of polygons encircling all clusters, and filling the medial square lattice of the original lattice [23, 24].

1 Partition Functions and Correlation Decay Our goal is to compute the total number of matchings in

a given graph. Toward that goal, we will define a generalization called partition function and then apply the technique of correlation decay that originates in statistical physics for estimating certain marginal probability distributions.

Any function $f: G \rightarrow \mathbb{R}$ is the partition function of some real vertex model if and only if f is weakly reflection positive. We prove this theorem in Section 5. It is not hard to show that if f is a partition function, then $f = f \circ c$ for some unique $n \in \mathbb{Z}^+$ and $c \in ((\mathbb{R}^n)^{\otimes 3})^{C_3}$, up to the natural action of the real orthogonal group $O(n)$ on c (which leaves $f \circ c$ invariant) — see Section 6.

2 Signed Graphs, Kostant Partition Functions, and Flows. In this section, we define the concepts of graphs, Kostant partition functions, and flows, all in the signed case. One can think of these as the generalization of these concepts’ signless counterparts from the type A_n (signless) root system to

other types, such as C_{n+1} and D_{n+1} . We also define general flow polytopes, which are the main object of this paper.
