The Reynolds-stress measurements demonstrate that the turbulence structure of the separated shear layer differs from that of a plane mixing layer between two streams in a number of ways. In particular, the normal stresses all rise monotonically as reattachment is approached, are always considerably higher than the plane layer values and develop in quite different ways.

When the gap ratio is above $G/H=0.2$, the turbulence statistics have large values in the lower shear layer. For the gap ratio $G/H \leq 0.1$, however, the lower shear layer displays small turbulence-statistics values and approach

those of the no-gap case ($G/H=0$) with increasing distance downstream. In the upper shear layer separated from the fence top, the turbulence statistics are nearly independent of the gap ratio.

Abstract Extensive visual and quantitative studies of turbulent boundary layers are described. Visual studies reveal the presence of surprisingly well-organized spatially and temporally dependent motions within the so-called 'laminar sublayer'. These motions lead to the formation of low-speed streaks in the region very near the wall.

Turbulent flow is a most important branch of fluid dynamics yet its complexity has tended to make it one of the least understood. Empirical data have been appearing rapidly for more than twenty years but a consistent theory of turbulent flow based on the results has been lacking. In recent years it has become increasingly evident that turbulent shear flows do contain structures or eddies whose description is more deterministic than had been thought, possessing identifiable characteristics, existing for significant lifetimes, and producing recognizable and important events.

A fundamental property of turbulent shear flow, related to its growth, is the phenomenon of entrainment, that is, the incorporation of nonlurbulent, usually irrotational fluid into the turbulent region or, conversely, the diffusion of the tur

Structure of Turbulent Shear Flows: A New Look

The presence of organized motions and structures in turbulent shear flows was apparent for a long time, and has been additionally implied by mixing length hypothesis even before the concept was explicitly stated in literature. There were also early correlation data found by measuring jets and turbulent wakes, particularly by Corrsin and Roshko.
