Reliability is a monotonic function of time and always decreases with time, which indicates that the loss of reliability is a common behavior for all devices. Since η and β always exceed zero, the value of $R(t)$ is always between 0 and 1, indicating that reliability can also be viewed as the probability of a failure to occur.

Structural ceramics are generally brittle, which seriously affects the reliability of ceramic components. Four methods are typically used to resolve this weakness: (a) fiber reinforcement or microstructural control to toughen the ceramic, (b) high-level non-destructive inspection and repair of the dangerous flaws, (c)

proof testing to select components with high reliability, and (d) using materials with self-crack-healing ability.
