The tutorial instructs readers how to conceptualize and design electric-field effects on bonds, structures, and reactions. Most effects can be comprehended as the field-induced stabilization of ionic structures. Thus, orienting the field along the “bond axis” will facilitate bond breaking. Similarly, orienting the field along the “reaction axis”, the direction in which “electron pairs transform” from reactants- to products-like, will catalyse the reaction.

Surface hydrides are ubiquitous in catalysis. However, their structures and properties are not as well-understood as those of their molecular counterparts, which have been extensively studied for the past 70 years. Hydrides isolated on surfaces have been characterized as stable entities on oxide surfaces or in zeolites. They have also been proposed as reaction intermediates in numerous ...

EEFs directly impact the structure of molecular systems. For example, aligning an electric field along a specific bond-axis leads to either shortening or elongation of the bond (and ultimately bond breaking). Furthermore, EEFs enable unprecedented control over chemical reactivity.

Chalcogen atoms (S, Se, and Te) play a pivotal role in determining molecular geometry, optical properties, and reactivity. Herein, new trichalcogenasumanenes (4–9) are synthesized, all with the benzylic carbons on sumanene replaced by two kinds of chalcogen atom. Crystallographic studies show that the molecular geometry varies from bowl-shaped (4 and 6) to planar (9) as the size of the majority chalcogen atom increases from S (4) to Se (6) to Te (9).
