In Field oriented control, stator field is continuously updated based on the position of the rotor field. By continuously pulling the rotor to a new position, the rotor is always magnetized with a new vector, thus reducing torque ripple. Applications where low speeds are required take advantage of this property of FOC.

Vector control, also called field-oriented control, is a variable-frequency drive control method in which the stator currents of a three-phase AC electric motor are identified as two orthogonal components that can be visualized with a vector. One component defines the magnetic flux of the motor, the other the torque. The control system of the drive calculates the corresponding current component references from the flux and torque references given by the drive's speed control. Typically proportio
