Contrast-enhanced ultrasound of focal liver masses

Contrast-enhanced ultrasound (CEUS) has evolved as a problem-solving tool for the characterization of focal liver lesions due to its noninvasive real-time imaging capability. Ultrasound contrast agents are intravenously injected microbubbles that are highly echogenic and oscillate in an ultrasound field to enhance ultrasound signal in gray scale, color, and spectral Doppler.

Contrast-Enhanced Ultrasound - an overview | ScienceDirect ...

The injection of microbubble ultrasound contrast agents improves the characterization of focal liver lesions that are indeterminate on conventional ultrasound. The use of CEUS is recommended in official guidelines and suggested as a second diagnostic step after ultrasound detection of indeterminate focal liver lesions to immediately establish the diagnosis, especially for benign liver lesions, such as hemangiomas, avoiding further and more expensive examinations.

Contrast-Enhanced Ultrasound of Focal Liver Lesions

Contrast-enhanced ultrasound (CEUS) is an imaging method that has been used in European and Asian countries for more than 10 years. The use of ultrasound contrast agents has been approved in several countries, but the Food and Drug Administration (FDA) in the United States has not yet approved their application for a noncardiac use.

Imaging characterization of focal liver lesions and exclusion of malignancy are of prime importance, particularly in high-risk populations. Contrast agent-enhanced ultrasonography of liver lesions is both accurate and reproducible for evaluation of benign and malignant liver tumors.

There may be differences in the measured values in comparison with ultrasonography without contrast enhancement, if the maximum flow rate (i.e., the upper limit of the Doppler spectral curve) is not detected because the signal strength is too low. 28, 32 This is often the case for pathological flow in small volumes (e.g., flow in a stenosis, reflux jet, or shunt flow).

Contrast-enhanced ultrasound (CEUS) is a safe, relatively inexpensive, and widely available imaging technique using dedicated imaging ultrasound sequences and FDA-approved contrast microbubbles that allow detection and characterization of malignant focal liver lesions with high diagnostic accuracy. Contrast-enhanced ultrasonography was performed with a ultrasound machine 1 with a 5–11 MHz broadband linear probe 1 or a 3.75 MHz convex probe. 1 A single focal zone was placed at the deepest part of the lesion. The MI was set at 0.1–0.2 MI to minimize microbubble destruction.
