Two other quantities that play a key role in Bayesian statistics are the prior and posterior predictive distributions: The prior predictive distribution is just the marginal distribution of the observed data if the parameter is integrated out $p(y) = \int p(y|\theta)\pi(\theta)d\theta$

$p(y|\theta)$ This is just the denominator in the posterior.

Bayesian inference is the application of the product and sum rules to real problems of inference. Applications of Bayesian inference are creative ways of looking at a problem through the lens of these two rules.

The first key element of the Bayesian inference paradigm is to treat parameters such as w as random variables, exactly the same as A and B . So the conditional probability now becomes $P(B|A;w)$, and the dependency of the probability of B on the parameter settings, as well as A , is made explicit.

Bayes' theorem is of fundamental importance to the field of data science, consisting of the disciplines: computer science, mathematical statistics, and probability. It is used to calculate the probability of an event occurring based on relevant existing information. Bayesian inference meanwhile leverages Bayes' theorem to update the probability of a hypothesis as additional data is encountered.
