A Punnett square is a simple method for determining the theoretical ratios of genotypes and phenotypes that would occur in the offspring of a cross between two parents. A monohybrid cross is when you are only looking at the genetic outcomes for a single gene. Steps.

How to Use a Punnett Square to Do a Monohybrid Cross

A monohybrid cross is a breeding experiment between P generation (parental generation) organisms that differ in a single given trait. The P generation organisms are homozygous for the given trait. However, each parent possesses different alleles for that particular trait. A Punnett square may be used to predict the possible genetic outcomes of a monohybrid cross based on probability.

Monohybrid Cross: A Genetics Definition

From punnett square in the offspring we have genotype ratio and probability: 1 (25%)GG : 2 (50%)Gg : 1 (25%)gg - this typical genotypes ratio (1:2:1) for a monohybrid cross. Dominant allele will mask the recessive allele that means, that the organisms with the genotypes "GG" and "Gg" have the same phenotype. For example, if allele "G" is yellow color and allele "g" is green color, then "gg" have green phenotype, "GG" and "Gg" have yellow phenotype.

Punnett Squares. A Punnett square is a chart that allows you to easily determine the expected percentage of different genotypes in the offspring of two parents. An example of a Punnett square for pea plants is shown in Figure below. In this example, both parents are heterozygous for flower color (Bb). The gametes produced by the male parent are at the top of the chart, and the gametes produced by ...

The key difference in monohybrid and dihybrid is of genetic arrangement. Monohybrid parents have only a single trait difference, when they are crossed or breed the process is so called monohybrid cross while in a dihybrid, parents have two trait difference and when they are crossed the process is dihybrid cross.
