Dynamic causal models. The dynamic causal model is a multiple-input multiple-output (MIMO) system that comprises m inputs and l outputs with one output per region. The m inputs correspond to designed causes (e.g. boxcar or stick stimulus-functions). The inputs are exactly the same as those used to form design matrices in conventional analyses of fMRI and can be expanded in the usual way when necessary (e.g. using polynomials or temporal basis functions).

The Rubin causal model, also known as the Neyman–Rubin causal model, is an approach to the statistical analysis of cause and effect based on the framework of potential outcomes, named after Donald Rubin. The name "Rubin causal model" was first coined by Paul W. Holland. The potential outcomes framework was first proposed by Jerzy Neyman in his 1923 Master's thesis, though he discussed it only in the context of completely randomized experiments. Rubin extended it into a general framework ...

The causal inference can be divided into three sub-areas: discovering the causal model from the data, identifying the causal effect when the causal structure is known and estimating an identifiable causal effect from the data. Our contribution belongs to the second category, identification of causal effects.

To move from a static representation to a dynamic interpretation of the relationships in the data, we need a causal model. In the social sciences, a causal model is often a theory grounded in some high-level interpretation of human behavior. However, a causal model does not need be a theory but can be any map that imposes a hierarchy between variables.

A causal model incorporating an ADMG and probability distribution satisfying MC d-separation is called a semi-Markov causal model (SMCM). If we allow that the correct causal graph may be an ADMG, we can still apply MC d -separation , and ask which graphs imply the same sets of conditional independence relations.

In philosophy of science, a causal model is a conceptual model that describes the causal mechanisms of a system. Causal models can improve study designs by providing clear rules for deciding which independent variables need to be included/controlled for. They can allow some questions to be answered from existing observational data without the need for an interventional study such as a randomized controlled trial. Some interventional studies are inappropriate for ethical or practical reasons, mea

Federica Russo Philosophy, Louvain & Kent. Abstract One of the goals of the social sciences is to explain social phenomena. In this explanatory enterprise, causal relations, established by means of the so-called ‘causal models’, play a major role. This paper advances the view that causal models, by modelling causal mechanisms, (ought to) provide an explanation of social phenomena and should be seen as a model of explanation.1.

Causal models incorporate the idea of multiple causality, that is, there can be more than one cause for any particular effect. For example, how a person votes may be related to social class, age, sex, ethnicity, and so on. Moreover, some of the independent or explanatory variables could be related to one another.

In a causal model of reactivity, the usefulness of laboratory assessment rests on the assumption that laboratory-based cardiovascular reactivity predicts responses in the natural environment. We find only limited generalizability and suggest that cardiovascular responses to stress can be better understood when examined in the natural environment.

If we build a causal model around this diagram, it has 2 real degrees of freedom - a degree of freedom for saying that the probability of an earthquake is, say, 29% (and hence that the probability of not-earthquake is necessarily 71%), and another degree of freedom for saying that the probability of a recession is 3% (and hence the probability of not-recession is constrained to be 97%).

The Neyman-Rubin model of causal inference helps to clarify some of the issues which arise. In this chapter, the model is briefly described, and some consequences of the model are outlined for both quantitative and qualitative research. The model has radical implications for work in the social sciences given current practices.

The structural equation model (SEM) entails the causal graph, in that you can reconstruct the causal graph by looking at the inputs of each function. It also entails the joint distribution, in that you can "sample" from an SEM by evaluating the functions in order, plugging in the random ϵ s where needed.

This part of the RCM focuses on the model-based analysis of observed data to draw inferences for causal effects, where the observed data are revealed by applying the assignment mechanism to the science. A full-length text that discusses estimation and inference for causal effects from this perspective is Imbens and Rubin (2006).

PCH organically emerges from a well-specified collection of causal mechanisms (a structural causal model, or SCM). We then turn to the logical lens. Our first result, the Causal Hierarchy Theorem (CHT), demonstrates that the three layers of the hierarchy almost always separate in a measure-theoretic sense.
