NMR uses a large magnet (Magnetic) to probe the intrinsic spin properties of atomic nuclei. Like all spectroscopies, NMR uses a component of electromagnetic radiation (radio frequency waves) to promote transitions between nuclear energy levels (Resonance). Most chemists use NMR for structure determination of small molecules.

Infrared (IR) Spectroscopy uses a beam of infrared light to analyze the structure of organic compounds. Whereas NMR analyzes the atoms present, IR instead analyzes the bonds present. NMR produces a set of sharp signals where every atom's signal may be discerned, but IR only produces broad absorptions which may frequently overlap.

NMR spectroscopy is the most common and comprehensive technique for studying the structure of organic molecules. In a broad sense, it still works by the same principle as other spectroscopies, and that is the interaction of the molecule with certain type of energy to produce different energy states and deduce information based on these differences. There is, however, a lot more information you can get from an NMR spectrum than what we have seen in the IR spectroscopy and Mass Spectrometry.
