In statistical theory, the field of high-dimensional statistics studies data whose dimension is larger than dimensions considered in classical multivariate analysis. High-dimensional statistics relies on the theory of random vectors. In many applications, the dimension of the data vectors may be larger than the sample size.

Behavioral scientists need powerful, effective analytic methods to glean maximum scientific insight from these data. Over the last few years, Runze Li and other statisticians have been developing new methods for analyzing high-dimensional data. Now, Center researchers are extending these methods for use in behavioral research focused on, for example, preventing drug abuse and HIV-risk behavior.

Dealing with high-dimensional data is a challenging issue, and the use of classical chemometric tools can lead to multivariate models influenced by a huge amount of variables, thus resulting of difficult interpretation. HSI data are an example of high-dimensional data, since each image is composed by tens of thousands of pixel spectra.

The blessings of dimensionality are less widely noted, but they include the concentration of measure phenomenon (so-called in the geometry of Banach spaces), which means that certain random fluctuations are very well controlled in high dimensions and the success of asymptotic methods, used widely in mathematical statistics and statistical physics, which suggest that statements about very high-dimensional settings may be made where moderate dimensions would be too complicated.

Clustering high-dimensional data is the cluster analysis of data with anywhere from a few dozen to many thousands of dimensions. Such high-dimensional spaces of data are often encountered in areas such as medicine, where DNA microarray technology can produce many measurements at once, and the clustering of text documents, where, if a word-frequency vector is used, the number of dimensions equals the size of the vocabulary.
