Room Equalization Based On Iterative

Equalization filters design based on iterative simple complex smoothing has been proposed for room equalization. The algorithm can be useful in cases of long duration acoustic impulse responses since it results in impulse

responses of reduced complexity which preserve the initial transient data that are significant to the listener.

For rectangular rooms with symmetric loudspeaker arrangements, full room equalization can be achieved at low frequencies, as demonstrated by previous research. The method is based on generating a plane wave that

propagates along the room. However, often the room is not rectangular, and/or a symmetric loudspeaker setup cannot be assured, leading to a deteriorated equalization performance.

This paper proposes a modified iterative equalization (MIE) scheme based on precoding. First we analyze and compare the performance of the improved MAX-Log-MAP (I-MLM) algorithm called MIE-I-MLM scheme and two traditional equalization algorithms in MIE scheme.
