The transfer of heat energy by conduction takes place within the

boundaries of a system, or a cross the boundary of the system into another system placed in direct physical contact with the first, without any appreciable displacement of matter comprising the system, or by the exchange of kinetic energy of motion of the molecules by direct communication, or by drift of electrons in the case of heat conduction in metals.

The heat transfer by convection requires a solid-fluid interface, a temperature difference between the solid surface and the surrounding fluid and a motion of the fluid. The process of heat transfer by convection would occur when there is a movement of macro-particles of the fluid in space from a region of higher temperature to lower temperature.

Heat transfer processes are classified into three types. The first is conduction, which is defined as transfer of heat occurring through intervening matter without bulk motion of the matter. Figure 1.1 shows the process pictorially. A solid (a block of metal, say) has one surface at a high temperature and one at a lower temperature.

If the mixture in the tube is stagnant, the mass transfer occurs by molecular diffusion. This is analogous to conduction in heat transfer. If there is bulk mixing by mechanical stirring or due to density differences, diffusion occurs due to forced or natural convection, called eddy diffusion which is indeed analogous to convection in heat transfer.
