Two primary classes of thermodynamic cycles are power cycles and heat pump cycles. Power cycles are cycles which convert some heat input into a

mechanical work output, while heat pump cycles transfer heat from low to high temperatures by using mechanical work as the input. Cycles composed entirely of quasistatic processes can operate as power or heat pump cycles by controlling the process direction.

Thermodynamic power cycles are the basis for the operation of heat engines, which run the vast majority of motor vehicles and generate most of the world’s electric power. Heat pump cycles. Heat pump cycles transfer heat from low to high temperatures using mechanical work input. There is no difference between thermodynamics of refrigerators and heat pumps. Both work by moving heat from a cold space to a warm space.

Classification of Thermodynamic Cycles

The analysis of all thermodynamic cycles (or air cycle) is based on the following assumptions: The gas in the engine is a perfect gas, that is, it obeys the gas laws and constant specific heats. The physical constant of the gas in the engine cylinder is the same as those of the air at a moderate temperature.

Hence, the working fluid doesn't undergo a thermodynamic cycle.In order to analyze this complex gas power cycles, air standard cycles are conceived. In air standard cycle a certain mass of air operates in a complete thermodynamic cycle where the heat is added and rejected using external reservoirs , and all the processes in the cycle are reversible .
