Wind tunnel derived wind loads can, in many circumstances, fall below code prescribed values. Wind tunnel model studies, therefore, frequently lead to cost savings. Other candidates for wind tunnel tests are buildings and structures that have an unusual sensitivity to the action of wind or that fall outside existing experience.

WIND TUNNEL STUDY Wind tunnel test on a section model had been carried out early in the 40's, e.g. on the Tacoma Narrows Bridge, and in later years workers such as van Nunen & Persoon[1982], Brownjohn & Choi[2001] also carried out tests to investigate wind effects on bridge decks. Sectional model testing was found to be a useful means to obtain the aerodynamic

Wind tunnel, device for producing a controlled stream of air in order to study the effects of movement through air or resistance to moving air on models of aircraft and other machines and objects. Provided that the airstream is properly controlled, it is immaterial whether the stationary model under testing is designed to move through the air, as an aircraft, or to withstand wind pressures while standing in place, as a building.

Wind tunnels are large tubes with air blowing through them. The tunnels are used to replicate the actions of an object flying through the air or moving along the ground. Researchers use wind tunnels to learn more about how an aircraft will fly. NASA uses wind tunnels to test scale models of aircraft and spacecraft. Some wind tunnels are large enough to contain full-size versions of vehicles. The wind tunnel moves air around an object, making it seem as if the object is really flying. Most of the

Almost all wind tunnel tests were and still are performed with scale models because wind tunnels capable of handling full-sized aircraft are simply too expensive. In a classic set of experiments, Osborne Reynolds (1842-1912) of the University of Manchester demonstrated that the airflow pattern over a scale model would be the same for the full-scale vehicle if a certain flow parameter were the ...

Abstract. L-shaped tall buildings are commonly built in urban areas due to shortage of land and graceful demand of architectural design. In this study, eight L-shaped rigid models with different geometric dimensions are tested in a boundary wind tunnel to study the characteristics of the wind-induced torques acting on L-shaped tall buildings. RMS force coefficients, power spectral densities and vertical correlation functions of the wind-induced torques are analyzed and discussed in details.

Model Wind Tunnel Tests. Wind tunnel tests should be carried out when wind loads are significant for overall stability, offset, motion, or structural response, or there is the danger of dynamic instability. Wind tunnel tests may support or replace theoretical calculations when available theoretical methods are susceptible to large uncertainties (e.g., due to a new type of installation or an adjacent installation that influences the relevant installation).

In building and environmental aerodynamics, wind tunnel studies of natural vegetative structures like bushes or trees have to be modelled. From a fluid mechanical point of view, these structures differ essentially from man-made constructions because of their structural flexibility and permeability.

Abstract Reynolds-number dependence of flow fields within a modelled urban area was studied in a wind tunnel. We measured flow around a single model building and around model city blocks at

various wind speeds, and studied Reynolds number indices more appropriate than the building Reynolds number. Our results led to the following conclusions.

Analysis of the above problems, and the experience accumulated from water tank and wind tunnel model studies of atmospheric convection at the Institute of Hydrology and Water Resources Planning (IHW), Karlsruhe University, (see paper by E. Plate in this volume), enabled the development of a concept of the thermally stratified wind tunnel with preshaped vertical temperature and velocity

profiles at the inlet of the test section.

In such situations, more accurate estimates of wind effects on the buildings are obtained through model tests in a boundary-layer wind tunnel, where the boundary layer is simulated by means of the 'roughness, barrier and mixing device' recommended by Cook [4.1]. A typical arrangement of the hardware in a wind tunnel is shown in Fig. 4.1.
