Martínez-Espinosa RM (1), Cole JA, Richardson DJ, Watmough NJ. The nitrogen cycle describes the processes through which nitrogen is converted between its various chemical forms. These transformations involve both biological and abiotic redox processes. The principal processes involved in the nitrogen cycle are nitrogen fixation, nitrification, nitrate assimilation, respiratory reduction of nitrate to ammonia, anaerobic ammonia oxidation (anammox) and denitrification.

All cyanobacterial mats that have been investigated have been proven to be diazotrophic, i.e., use atmospheric dinitrogen (N (2)) as the source of nitrogen. Many cyanobacteria possess the capacity to fix N (2) and different species have evolved various ways to cope with the sensitivity of nitrogenase toward oxygen which is produced by these oxygenic phototrophs.

When nitrogen fertilizer is applied a small percentage—1 to 2%—is converted to nitrous oxide, which escapes to the atmosphere, where it acts as a powerful greenhouse gas. As a diazotroph, Trichodesmium contributes a large portion of the marine ecosystem’s new nitrogen, estimated to produce between 60 and 80 Tg of nitrogen per year. Nitrogen fixed by Trichodesmium can either be used directly by the cell, enter the food chain through grazers, be released into dissolved pools, or get exported to the deep sea.

Plants take up protein, as a nitrogen source, and other nutrients in their roots, stems, and aerial tissues (60 – 62). Endophytic bacteria and bacterial communities that fix nitrogen and fight plant diseases have been described (61, 63, 64). Plants may conceivably take up prions from soil or water into their root systems or aerial tissues or become surface contaminated through saliva, urine, feces, and/or decaying CWD-infected carcasses.
