The Butterworth filter design can be implemented digitally based on two methods matched z-transform and bilinear transform. An analog filter design can be discretized using these two methods. If we consider Butterworth filter which has all-pole filters, then both the methods impulse variance and matched z-transform are said to be equivalent.

The basic concept of a filter can be explained by examining the frequency dependent nature of the impedance of capacitors and inductors. Consider a voltage divider where the shunt leg is a reactive impedance. As the frequency is changed, the value of the reactive

impedance changes, and the voltage divider ratio changes.

Design and Analysis of Analog Filters: A Signal Processing Perspective includes signal processing/systems concepts as well as implementation. While most

books on analog filter design briefly present the signal processing/systems concepts, and then concentrate on a variety of filter implementation methods, the present book reverses the emphasis, stressing signal processing concepts.

Note: Most of these filters allow either double- or single-precision computation. Double-precision should be used unless the DSP is running out of resources. Single-precision should not be used for signal content below 1/10 the sampling frequency (5kHz for a typical 48kSPS system), or for high-Q filters.
